Continuation of 11. does NOT place the application in condition for allowance because: On pages 8-10 of the Applicants' Response, Applicants state that Chen et. al. does not describe that the failure message includes status information indicating that a switch in the data network is discarding frames or cells. Applicants state that Chen does not describe how to determine with any amount of certainty that the network device has indeed failed.

Examiner respectfully disagrees in that while Chen does state that the failure notification can be sent when there is a failed link or failed device, it would have been obvious that the conditions are similar. Chen states that when there is a failed device, the techniques used with regard to the failed link can be used with regard to the failed device (A network device receives a failure message from another device that has detected a failure. The message indicates that there is a failure at another device; See [0007] lines 1-3 and [0023] lines 1-8). This technique is of sending a failure message to the source indicating that a network device has failed (The control processing section is operable to detect a failure along a link or interface making up a part of a primary path. The interface is interpreted as an interface of the network device that has failed, therefore the message would indicate which particular node has failed. The control processing section is further operable to generate a failure message and to send it on to a source network device; See Fig. 5, #510; [0039] lines 7-9 and 17-19). This causes the source to perform a re-routing technique so as to avoid the failed device and prevent further packet loss ([0021] lines 1-15). When a packet sent to a failed device, gets dropped, this indicates that the link or device is no longer active. Since Chen incorporates sending a failure notification message back to the source, it would have been suggested by this message which device has failed.
